Constraint Satisfaction Problems (CSP)

Constraint Satisfaction Problems

Outline

- CSP examples
- Backtracking search for CSPs
- Problem structure and problem decomposition

Standard search problem

 state, successor function, heuristic and goal test are problemspecific

CSP

- state is defined by variables X_i with values from domain D_i
- goal test is to satisfy a set of constraints on variables

Constraint Satisfaction Problem

Formally:

$$X_1, X_2, ..., X_n$$
 --variables

$$C_1, C_2, ..., C_m$$
 --constraints

Each X_i takes values on domain D_i

Each C_i involves some variables

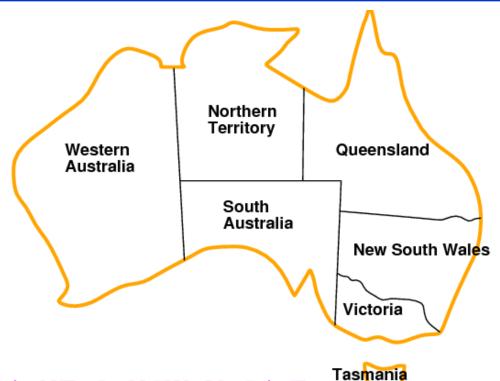

A state is an assignment

$$\{X_i = V_i, X_i = V_i, ...\}$$

such that constraints are satisfied.

A solution or goal is a complete assignment that satisfies all the constraints.

Example: Map-Coloring

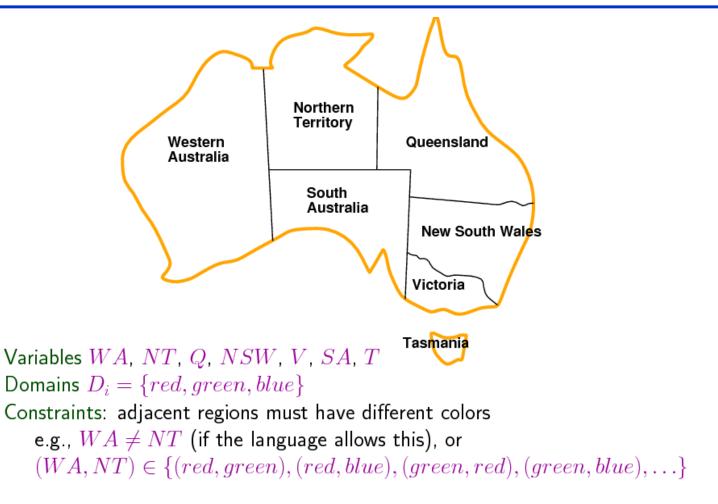

Variables WA, NT, Q, NSW, V, SA, T

Domains $D_i = \{red, green, blue\}$

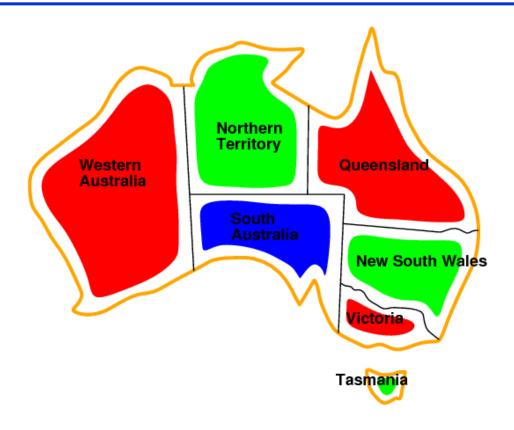

Constraints: adjacent regions must have different colors e.g., $WA \neq NT$ (if the language allows this), or $(WA, NT) \in \{(red, green), (red, blue), (green, red), (green, blue), \ldots\}$

Example: Map-Coloring

- How many solutions are there?

Example: Map-Coloring

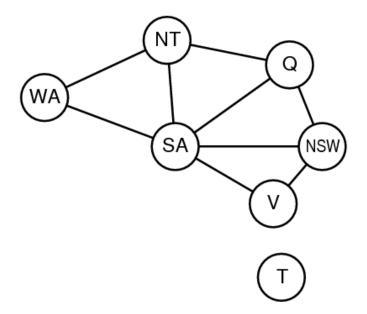

Solutions are assignments satisfying all constraints, e.g.,

 $\{WA = red, NT = green, Q = red, NSW = green, V = red, SA = blue, T = green\}$

Constraint graph

Binary CSP: each constraint relates at most two variables

Constraint graph: nodes are variables, arcs show constraints

General-purpose CSP algorithms use the graph structure to speed up search. E.g., Tasmania is an independent subproblem!

Examples of CSPs

- Place k knights on a $n \times n$ chessboard such that no two knights are attacking each other, where $k \le n^2$
 - Variables
 - Domains
 - Constraints

Examples of CSPs

- Sudoku
 - Variables how many?
 - Domain empty vs. full cells
 - Constraints
 - All different in column
 - All different in row
 - All different in "box of 9 cells"

				2	8		7	
			З					8
		8			1			8 4
	4					7		6
	8		7	5	6		4	
5		7					1	
9			8			6		
ø					9			
	2		5	4				

Examples of CSPs

- Cryparythmetic
 - Equation among unknown numbers, whose digits are represented by letters.

Goal: identify the value of each letter

All letters must have assigned different values

Varieties of CSPs

Discrete variables

- finite domains; size $d \Rightarrow O(d^n)$ complete assignments
- - ♦ e.g., job scheduling, variables are start/end days for each job
 - \diamondsuit need a constraint language, e.g., $StartJob_1 + 5 \le StartJob_3$
 - linear constraints solvable, nonlinear undecidable

Continuous variables

- e.g., start/end times for Hubble Telescope observations
- Iinear constraints solvable in poly time by LP methods

Varieties of constraints

Unary constraints involve a single variable,

e.g.,
$$SA \neq green$$

Binary constraints involve pairs of variables,

e.g.,
$$SA \neq WA$$

Higher-order constraints involve 3 or more variables,

e.g., cryptarithmetic column constraints

Preferences (soft constraints), e.g., red is better than green often representable by a cost for each variable assignment

→ constrained optimization problems

Real-world CSPs

Assignment problems

e.g., who teaches what class

Timetabling problems

e.g., which class is offered when and where?

Hardware configuration

Spreadsheets

Transportation scheduling

Factory scheduling

Floorplanning

Notice that many real-world problems involve real-valued variables

Standard search formulation (incremental)

Let's start with the straightforward, dumb approach, then fix it

States are defined by the values assigned so far

- ♦ Initial state: the empty assignment, { }
- Successor function: assign a value to an unassigned variable that does not conflict with current assignment.
 - ⇒ fail if no legal assignments (not fixable!)
- ♦ Goal test: the current assignment is complete
- 1) This is the same for all CSPs! 😂
- 2) Every solution appears at depth n with n variables
 - ⇒ use depth-first search
- 3) Path is irrelevant, so can also use complete-state formulation
- 4) $b = (n \ell)d$ at depth ℓ , hence $n!d^n$ leaves!!!!

Backtracking search

Variable assignments are commutative, i.e.,

$$[WA = red \text{ then } NT = green]$$
 same as $[NT = green \text{ then } WA = red]$

Only need to consider assignments to a single variable at each node

$$\Rightarrow b = d$$
 and there are d^n leaves

Depth-first search for CSPs with single-variable assignments is called backtracking search

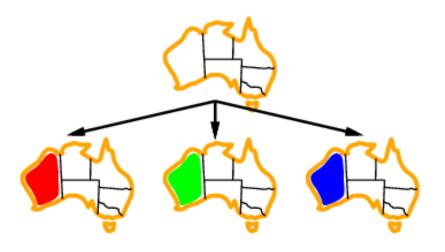

Backtracking search is the basic uninformed algorithm for CSPs

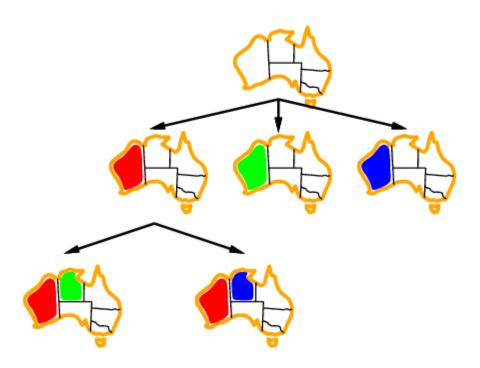

Can solve n-queens for $n \approx 25$

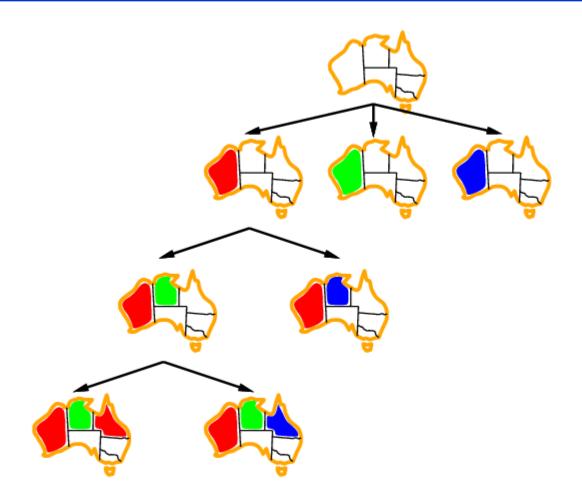

Backtracking search

```
function Backtracking-Search(csp) returns solution/failure
  return Recursive-Backtracking({ }, csp)
function Recursive-Backtracking (assignment, csp) returns soln/failure
  if assignment is complete then return assignment
  var \leftarrow \text{Select-Unassigned-Variable}(\text{Variables}[csp], assignment, csp)
  for each value in Order-Domain-Values (var, assignment, csp) do
       if value is consistent with assignment given CONSTRAINTS[csp] then
           add \{var = value\} to assignment
           result \leftarrow Recursive-Backtracking(assignment, csp)
           if result \neq failure then return result
           remove \{var = value\} from assignment
  return failure
```

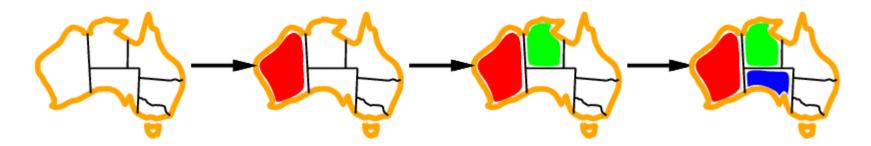

Improving backtracking efficiency

General-purpose methods can give huge gains in speed:

- 1. Which variable should be assigned next?
- 2. In what order should its values be tried?
- 3. Can we detect inevitable failure early?
- 4. Can we take advantage of problem structure?

Minimum remaining values

Minimum remaining values (MRV): choose the variable with the fewest legal values

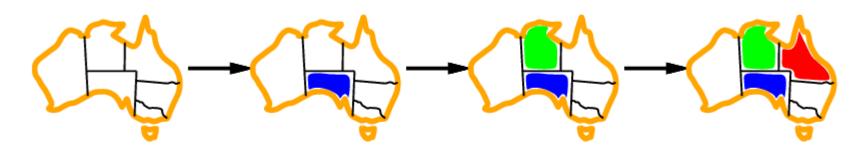

Degree heuristic

Tie-breaker among MRV variables

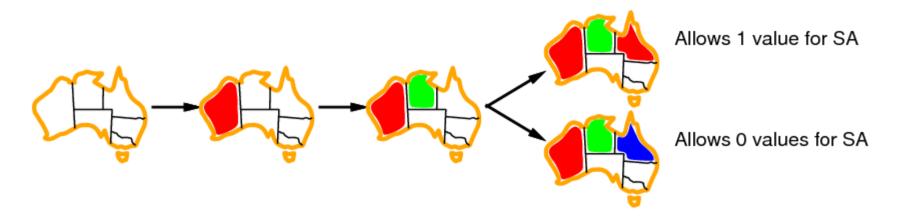

Degree heuristic:

choose the variable with the most constraints on remaining variables

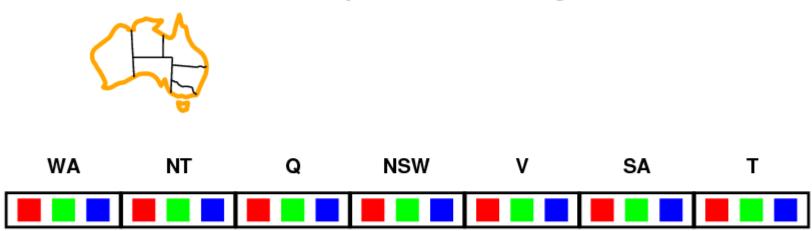

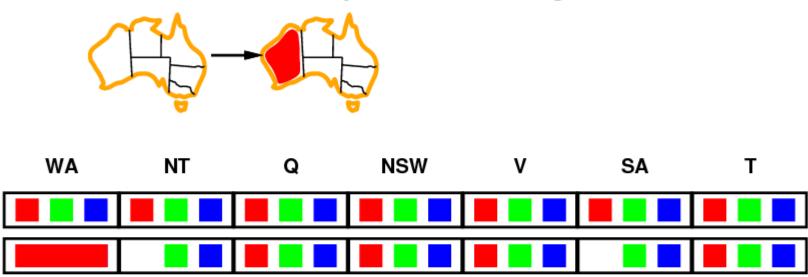

Least constraining value

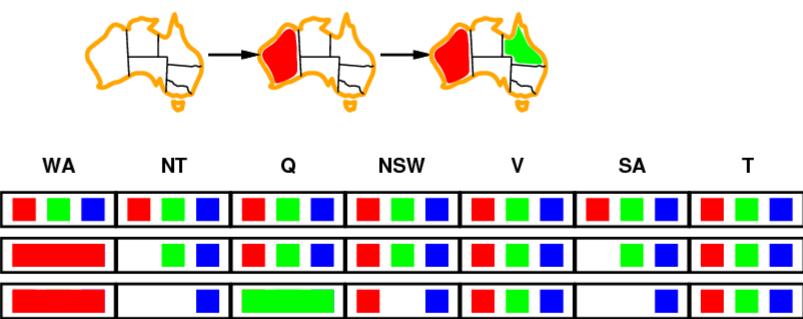

Given a variable, choose the least constraining value: the one that rules out the fewest values in the remaining variables

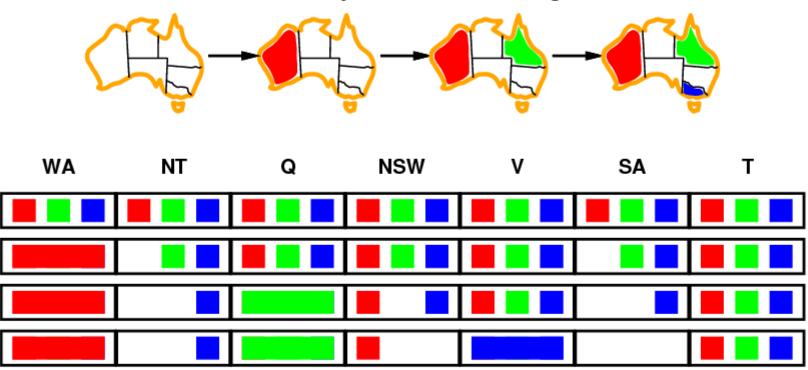

Combining these heuristics makes 1000 queens feasible

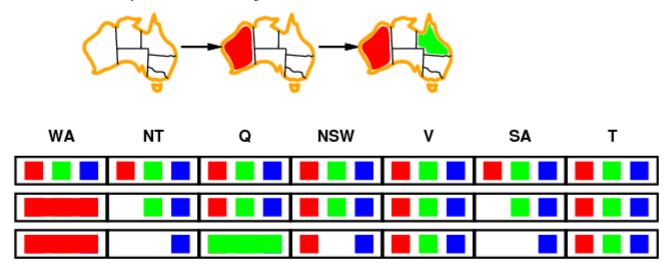

Constraint propagation

Forward checking propagates information from assigned to unassigned variables, but doesn't provide early detection for all failures:

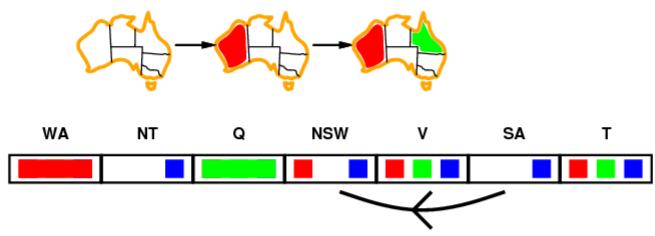

NT and SA cannot both be blue!

Constraint propagation repeatedly enforces constraints locally

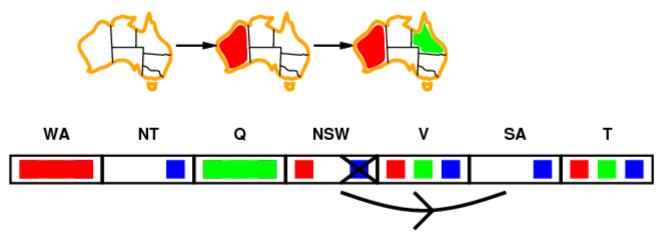

Simplest form of propagation makes each arc consistent

 $X \to Y$ is consistent iff for \mathbf{every} value x of X there is \mathbf{some} allowed y

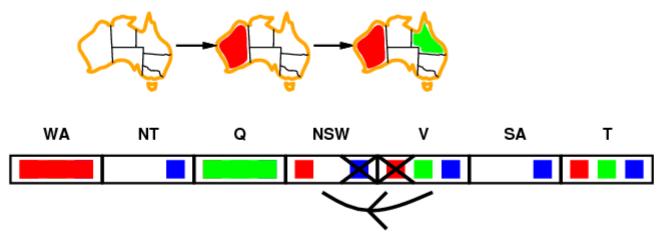

Simplest form of propagation makes each arc consistent

 $X \to Y$ is consistent iff for **every** value x of X there is **some** allowed y

Simplest form of propagation makes each arc consistent

 $X \to Y$ is consistent iff for **every** value x of X there is **some** allowed y

If X loses a value, neighbors of X need to be rechecked

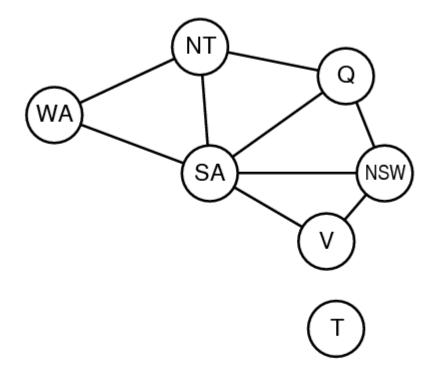

Simplest form of propagation makes each arc consistent

 $X \to Y$ is consistent iff for **every** value x of X there is **some** allowed y

If X loses a value, neighbors of X need to be rechecked Arc consistency detects failure earlier than forward checking Can be run as a preprocessor or after each assignment

Problem structure

Tasmania and mainland are independent subproblems

Identifiable as connected components of constraint graph

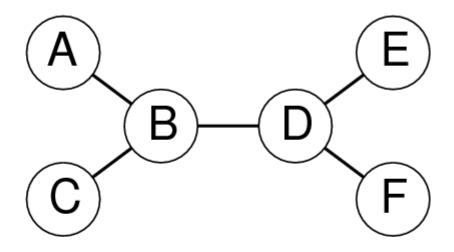

Problem structure contd.

Suppose each subproblem has c variables out of n total

Worst-case solution cost is $n/c \cdot d^c$, **linear** in n

E.g.,
$$n=80$$
, $d=2$, $c=20$
 $2^{80}=4$ billion years at 10 million nodes/sec
 $4\cdot 2^{20}=0.4$ seconds at 10 million nodes/sec

Tree-structured CSPs

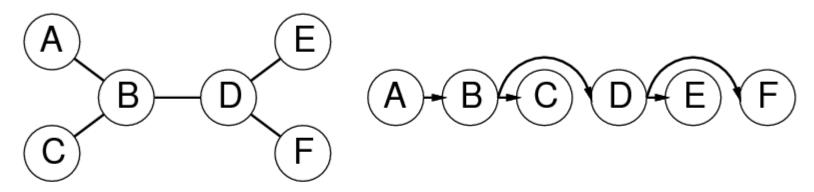

Theorem: if the constraint graph has no loops, the CSP can be solved in $O(n\,d^2)$ time

Compare to general CSPs, where worst-case time is $O(d^n)$

This property also applies to logical and probabilistic reasoning: an important example of the relation between syntactic restrictions and the complexity of reasoning.

Algorithm for tree-structured CSPs

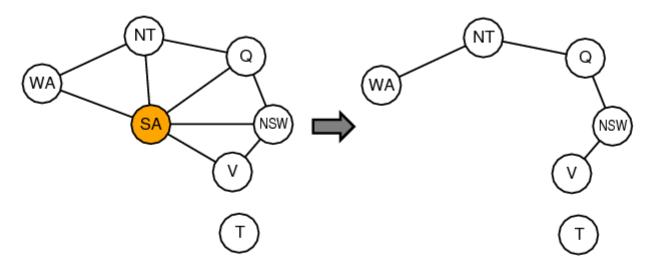

1. Choose a variable as root, order variables from root to leaves such that every node's parent precedes it in the ordering

- 2. For j from n down to 2, apply RemoveInconsistent($Parent(X_j), X_j$)
- 3. For j from 1 to n, assign X_i consistently with $Parent(X_i)$

Nearly tree-structured CSPs

Conditioning: instantiate a variable, prune its neighbors' domains

Cutset conditioning: instantiate (in all ways) a set of variables such that the remaining constraint graph is a tree

Cutset size $c \Rightarrow \text{runtime } O(d^c \cdot (n-c)d^2)$, very fast for small c

Summary

CSPs are a special kind of problem: states defined by values of a fixed set of variables goal test defined by constraints on variable values

Backtracking = depth-first search with one variable assigned per node

Variable ordering and value selection heuristics help significantly

Forward checking prevents assignments that guarantee later failure

Constraint propagation (e.g., arc consistency) does additional work to constrain values and detect inconsistencies

The CSP representation allows analysis of problem structure

Tree-structured CSPs can be solved in linear time
